Most genes contain the information needed to make functional molecules called proteins. (A few genes produce other molecules that help the cell assemble proteins.) The journey from gene to protein is complex and tightly controlled within each cell. It consists of two major steps: transcription and translation.

Genes, conventionally, are always written in italic (e.g. SHH) which is not the case for proteins (in the former example SHH). That should allow you to tell apart gene and protein symbols (SHH vs SHH). The capitalization of gene/protein names is a bit more in the grey area.

The central dogma of molecular biology is an explanation of the flow of genetic information within a biological system. It is often stated as "DNA makes RNA, and RNA makes protein", although this is not its original meaning. It was first stated by Francis Crick in 1957, then published in 1958:

The scope of a gene/protein article is the human gene/protein (including all splice variants derived from that gene) as well as orthologs (as listed in HomoloGene) that exist in other species.

Our research focuses on the three-dimensional structure of proteins, nucleic acids and their complexes with the aim to further our understanding of several essential mechanisms in the cell. We use a number of molecular biology and structural biology techniques, with a focus on X-ray diffraction crystallography. Our approach usually starts with the cloning of relevant genes and the expression ...
